

Browser Agent for Automated Multi-Item Returns

Field	Detail
Type	Browser automation agent
Platforms in scope	Amazon, Flipkart
Priority	To be set

Brand Details:

Flipkart: [Test Orders](#)

Login credentials: 9205359199 / OTP (Request OTP by calling 9205359199 to login)

1. Objective

Build a browser-based agent that reads pending return tasks from Excel, places the returns on the relevant e-commerce platform on our behalf, and writes the outcome back to Excel per line item. They must operate reliably across platforms that handle multi-item orders differently, and must run without getting flagged or blocked by the platforms as a bot.

2. Background & Context

A single order (OrderID #X) can contain multiple products / SKUs. Each line item has its own return window and its own return ID. The way a return is placed depends on the platform:

- **Batch flow** (e.g. Amazon) — one return flow can cover all items in the order.
- **Sequential flow** (e.g. Amazon, Flipkart) — the agent repeats the return micro-flow once per line item.

The agent must detect which model applies and follow the correct path, then record the result for every individual line item — never just the order as a whole.

3. End-to-End Agent Workflow

The agent runs the following loop for each task in Excel:

1. Read the next pending return task from Excel (status = "To Do" / "Pending").
2. Open a new browser window/tab for the platform named in that record (Amazon, Flipkart, etc.).
3. Initiate the return: select a return reason, pick a refund/pickup option, and confirm.
4. Capture the return ID, status, and refund amount returned by the platform.
5. Switch back to Excel and write the result back against that line item.
6. Mark the task as Done (or flag for human review if it could not be completed).

4. Excel Write-Back (Per Line Item)

Write-back must happen at the line-item level, not the order level. Each SKU on an order is its own row / record, and each gets its own outcome.

Field	Written by	Notes
Platform	Input (pre-filled)	Amazon / Flipkart / Amazon, etc.
Order ID	Input (pre-filled)	Used to locate the order
Product / SKU	Input (pre-filled)	Used to match the line item
Return window	Input / verified	Used for eligibility check
Return ID	Agent	Captured from the platform
Return status	Agent	Placed / Failed / Out of window
Refund amount	Agent	As shown by the platform
Task status	Agent	Done / Needs human review
Timestamp / log	Agent	When the action ran; error note if any

5. Partial-Success Handling

An order may succeed partially — some items return cleanly while others cannot (for example, one item is past its return window). The agent must never abandon the whole order because one item failed.

- Process each line item independently.
- If an item is out of window or otherwise ineligible: log it, set its status accordingly, and continue with the remaining items.
- Complete the items that are eligible (e.g. place returns for A and B even if C fails).
- Flag the failed/skipped items for human review rather than silently dropping them.
- Only mark the order fully Done when every line item has a final recorded state.

6. Bot-Detection Avoidance (Bonus)

Because the agent drives real e-commerce sites in a browser, the platforms may flag and block it as a bot. The agent must be built to behave like a legitimate human session.
